Nuclear Spectroscopic Telescope Array

The first hard X-ray focusing telescope in orbit

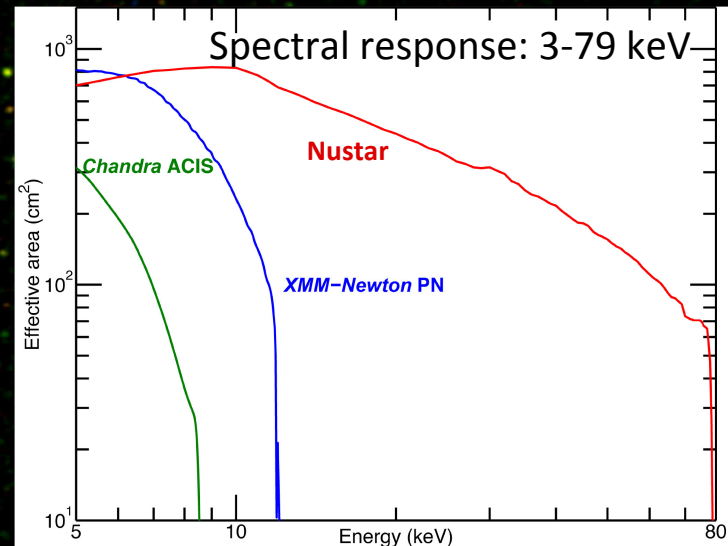

PI: Fiona Harrison
Launched on June, 13 2012

NASA senior review 2014: extension approved for 2+2 years

NuSTAR characteristics

- Focuses X-rays up to 79 keV
- FoV: 12.5' x 12.5'
- FWHM: 18"
- HPD: 58"
- Localization: 2.5" (1σ)

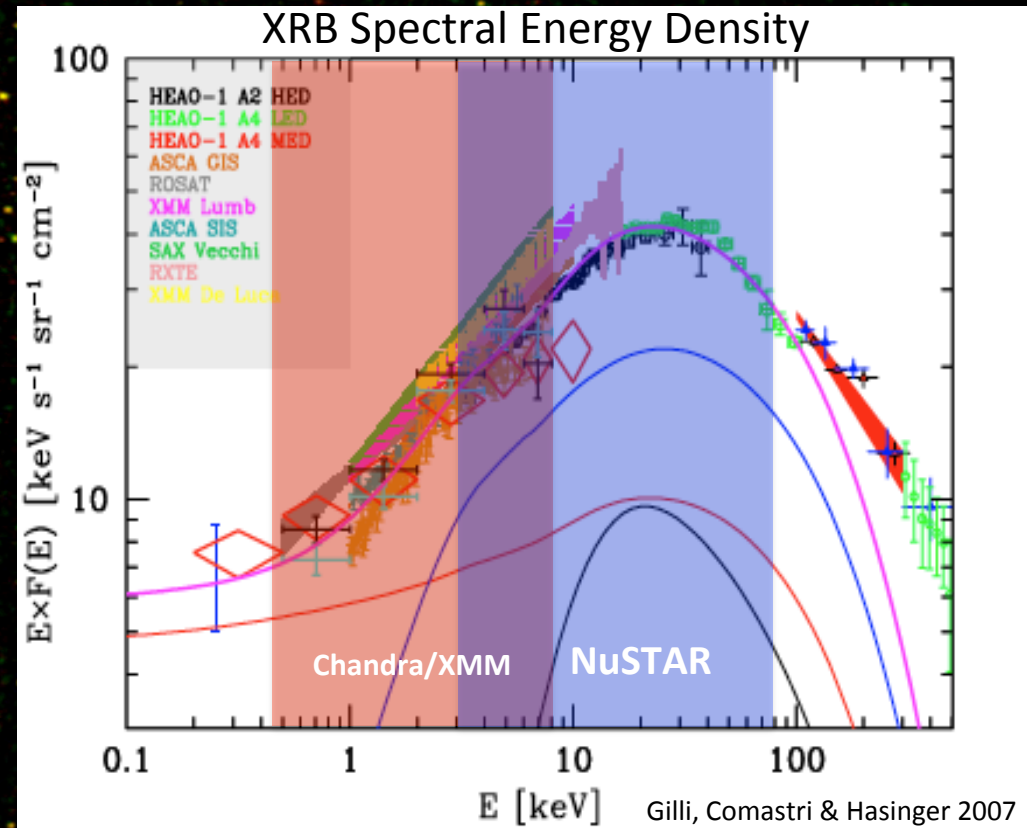

Improvements wrt previous hard X-ray instruments (Swift-BAT, Integral)

- Better spatial resolution (sub-arcmin)
- Better sensitivity (> 100x)

Allows to resolve a consistent fraction of the X-ray Background (XRB) @ > 10 keV

X-ray Background with NuSTAR

- Insights on the composition of the XRB peak at 20-30 keV by resolving 30-50% of the sources through direct detection and stacking
- NuSTAR almost not biased by obscured sources
 - Evolution of the active phase and obscuration with redshift

Multi-tiered approach: the Wedding Cake

Deep/narrow:

- E-CDF-S: ~ 200 ks/pointing over 0.3 deg^2
 - EGS: ~ 200 ks/pointing over 0.18 deg^2
- Mullaney et al. in prep., Aird et al. in prep.*

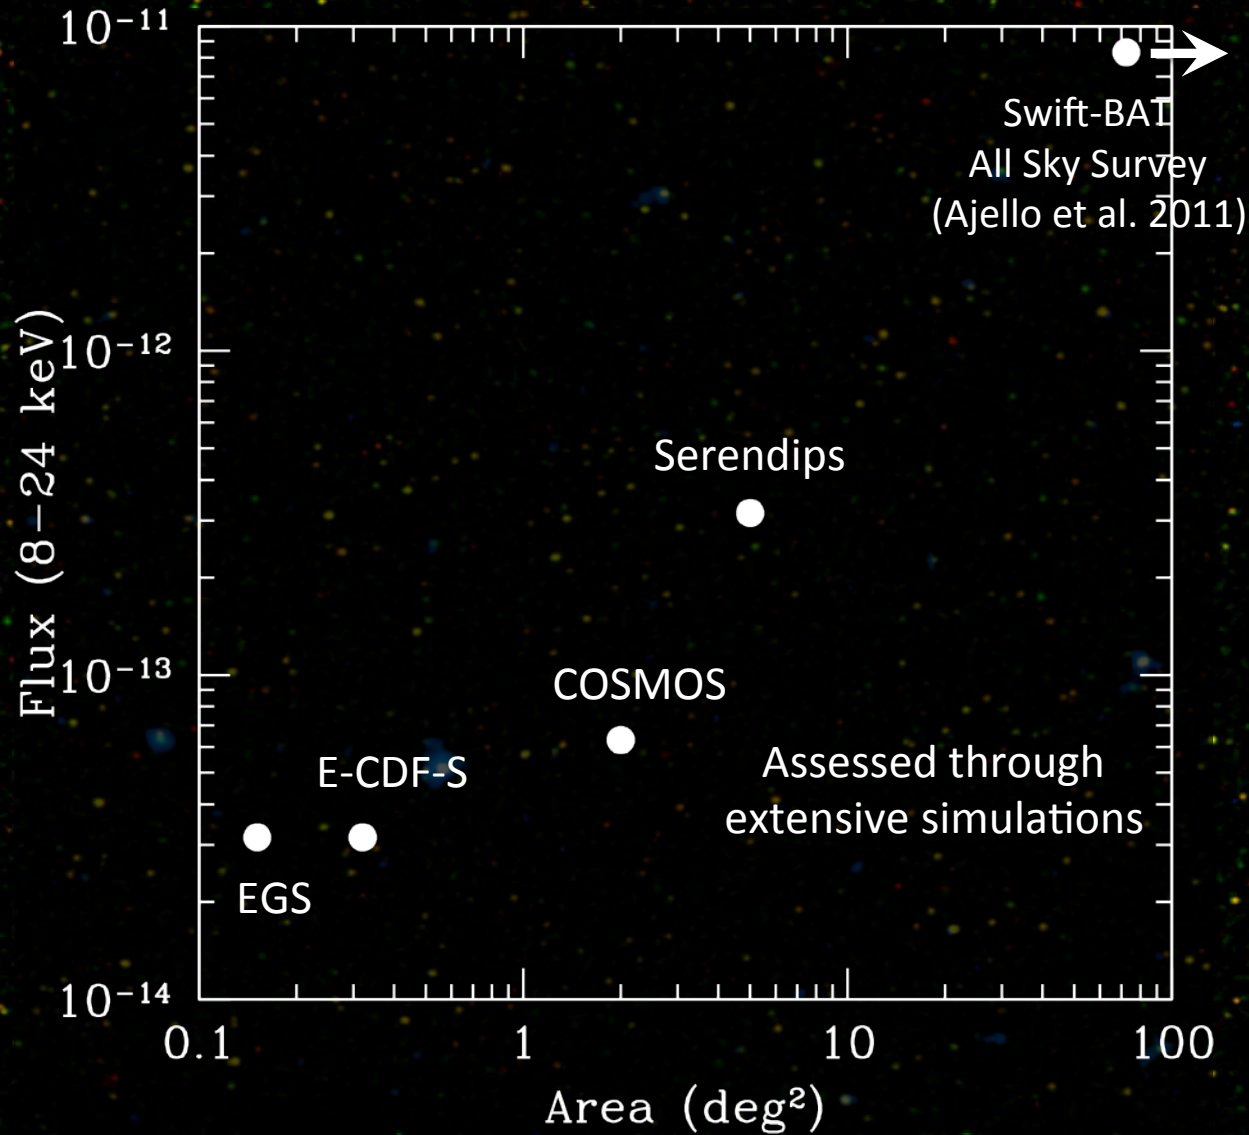

Medium:

- COSMOS: ~ 25 ks/pointing over $\sim 2 \text{ deg}^2$
- Civano et al. in prep*

Wide/Shallow:

- 100 Swift-BAT AGN fields
 - All NuSTAR targeted fields
- } $\sim 4\text{-}5 \text{ deg}^2$
- Alexander et al. 2013, Landsbury et al. in prep.*

NuSTAR Survey Sensitivity

Spectral analysis

Zappacosta et al. in prep.

- Sample selection
 - COSMOS+ECDF-S (2 deg²)
 - Flux limited sample $\rightarrow F(8-24 \text{ keV}) \geq 7 \cdot 10^{-14} \text{ erg s}^{-1} \text{ cm}^{-2}$
 - 35 objects (31 from COSMOS + 4 from ECDF-S)
 - COSMOS objects analyzed so far – ECDF-S analysis is on-going
- Nustar only modeling: 3-24 keV
- Joint broad-band Nustar+Chandra+XMM modeling: 0.5-24 keV
- Model for Nustar and broad band unabsorbed fits ($N_{\text{H}} < 10^{22} \text{ cm}^{-2}$):
absorbed power-law + Fe K α + Compton reflection ([model A](#))
- Model for broad-band fits for absorbed ($N_{\text{H}} > \sim 10^{22} \text{ cm}^{-2}$) sources
Scattered power-law + absorbed power-law + Fe K α + Compton reflection ([model B](#))

NuSTAR COSMOS survey

- 1.7 deg² → same area covered by Chandra XVP (PI: F. Civano) just completed
- 2 observing periods: 2013 and 2014
- 3.2 Ms exposure
- 20-30 ks exposure/tile
- 121 tiles (11x11 grid with half field shift)
- 100ks uniform depth on 1.1 deg²

Civano et al. in prep.

NuSTAR COSMOS survey

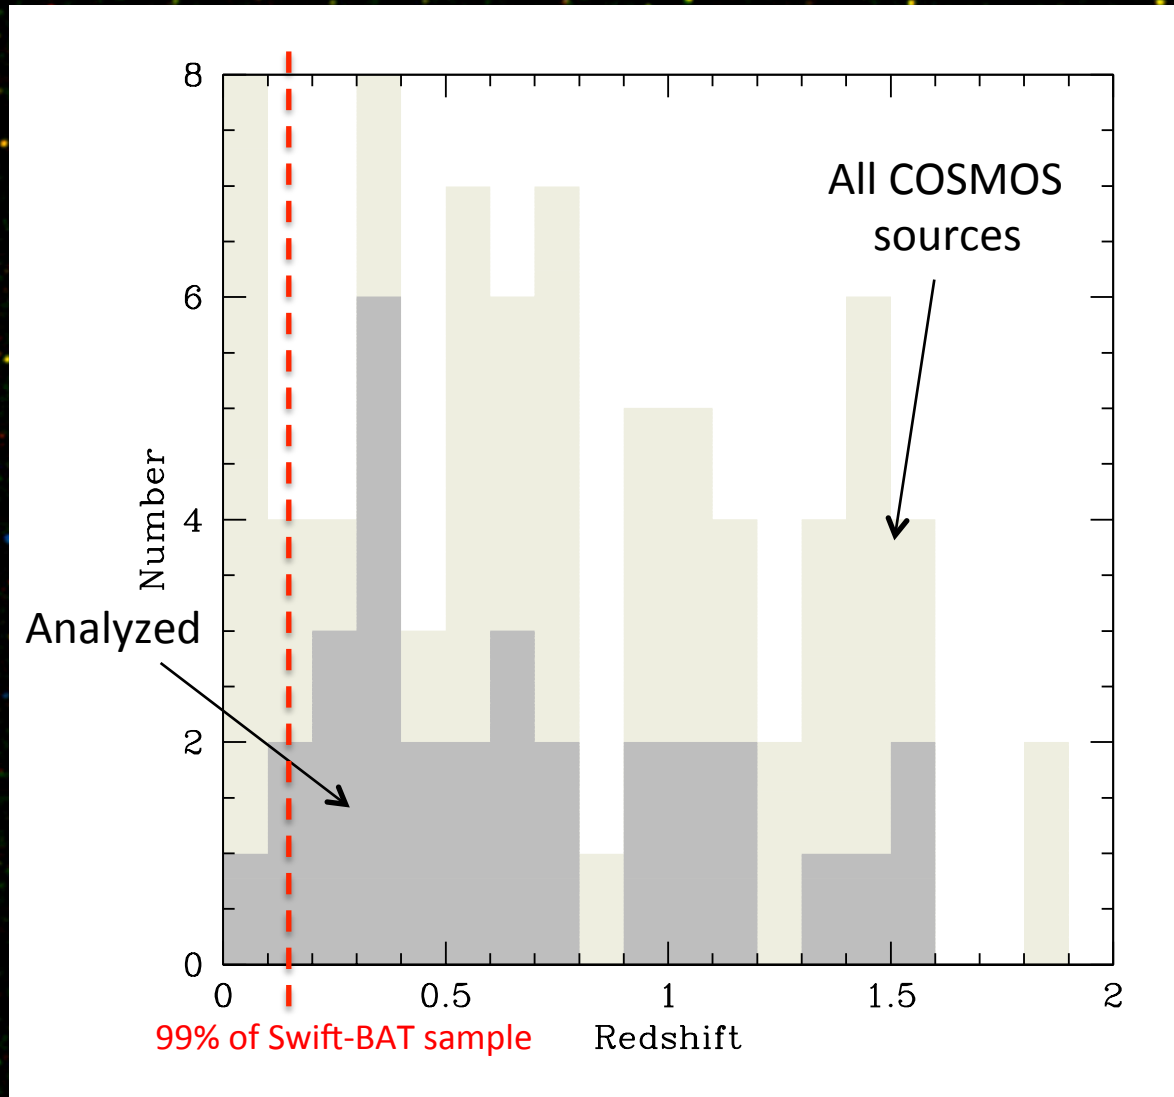

- 1.7 deg² → same area covered by Chandra XVP (PI: F. Civano) just completed
- 2 observing periods: 2013 and 2014
- 3.2 Ms exposure
- 20-30 ks exposure/tile
- 121 tiles (11x11 grid with half field shift)
- 100ks uniform depth on 1.1 deg²

91 sources detected

Civano et al. in prep.

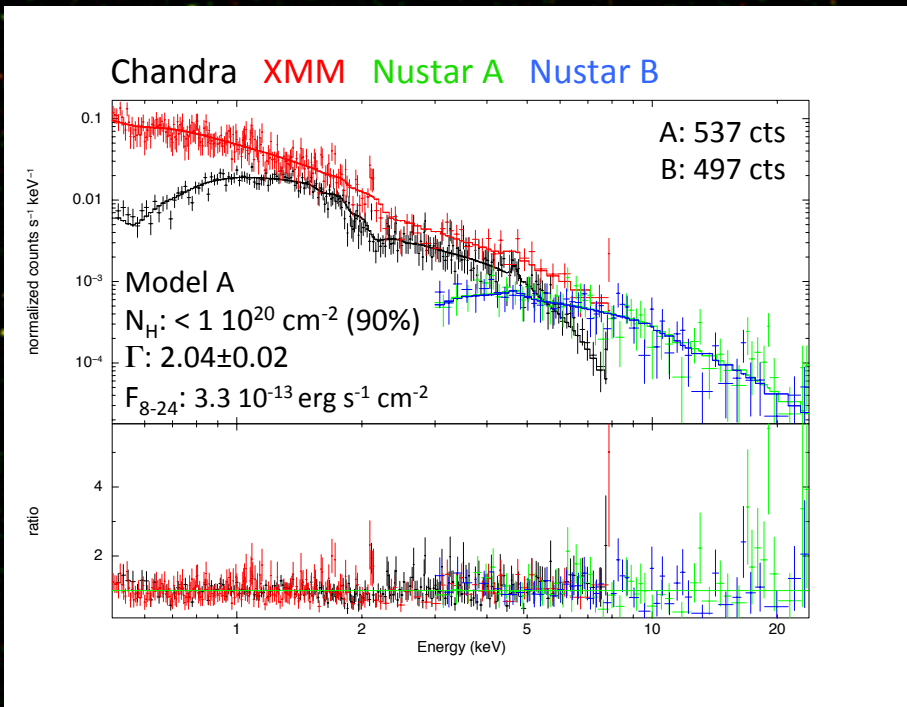

Redshift distribution

Spectra: low- N_H low-z source

Broad band Nustar+Chandra+XMM

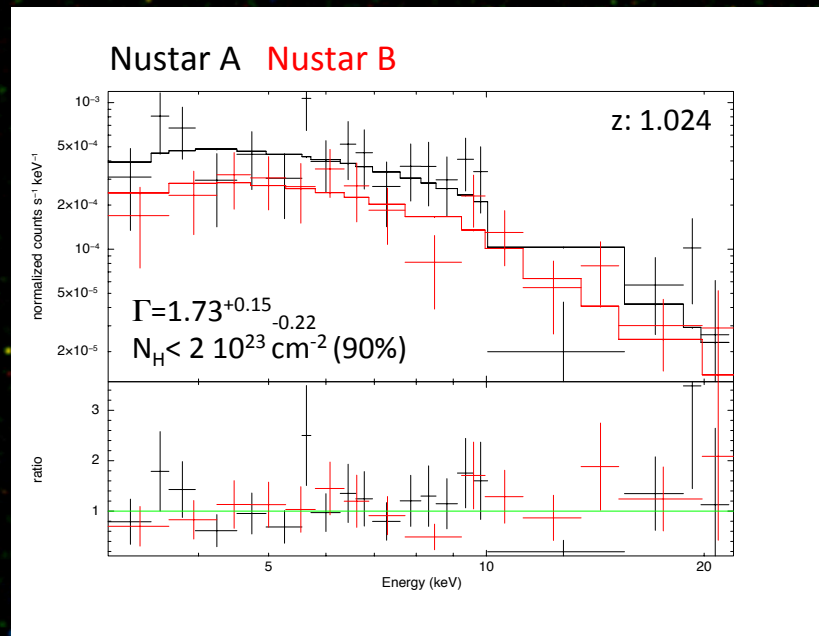

Nustar only

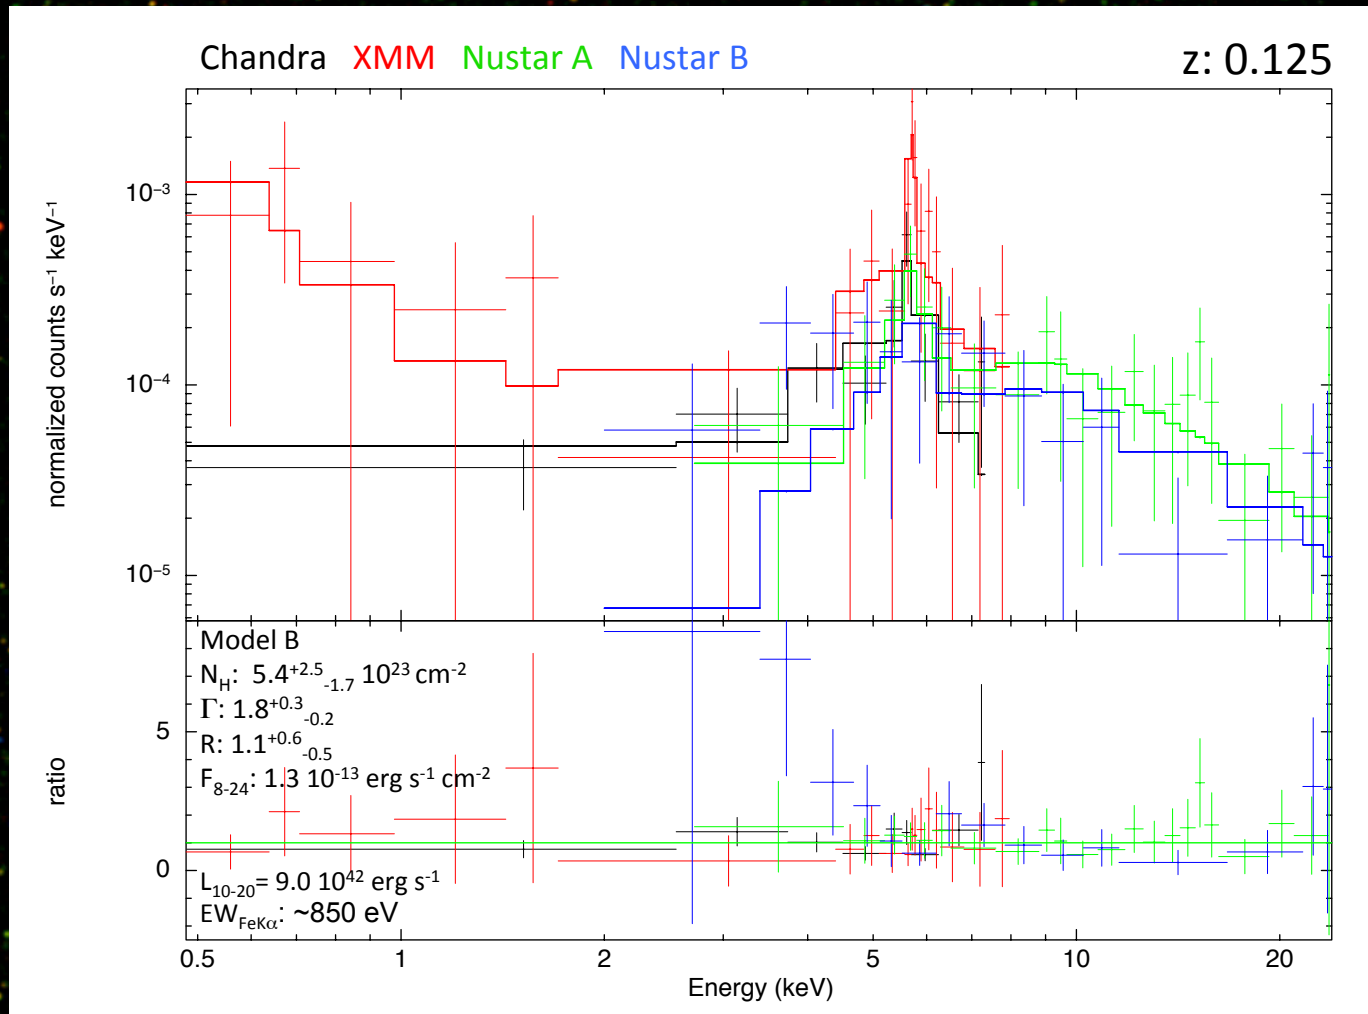

Spectra: low- N_H high-z source

Broad band Nustar+Chandra+XMM

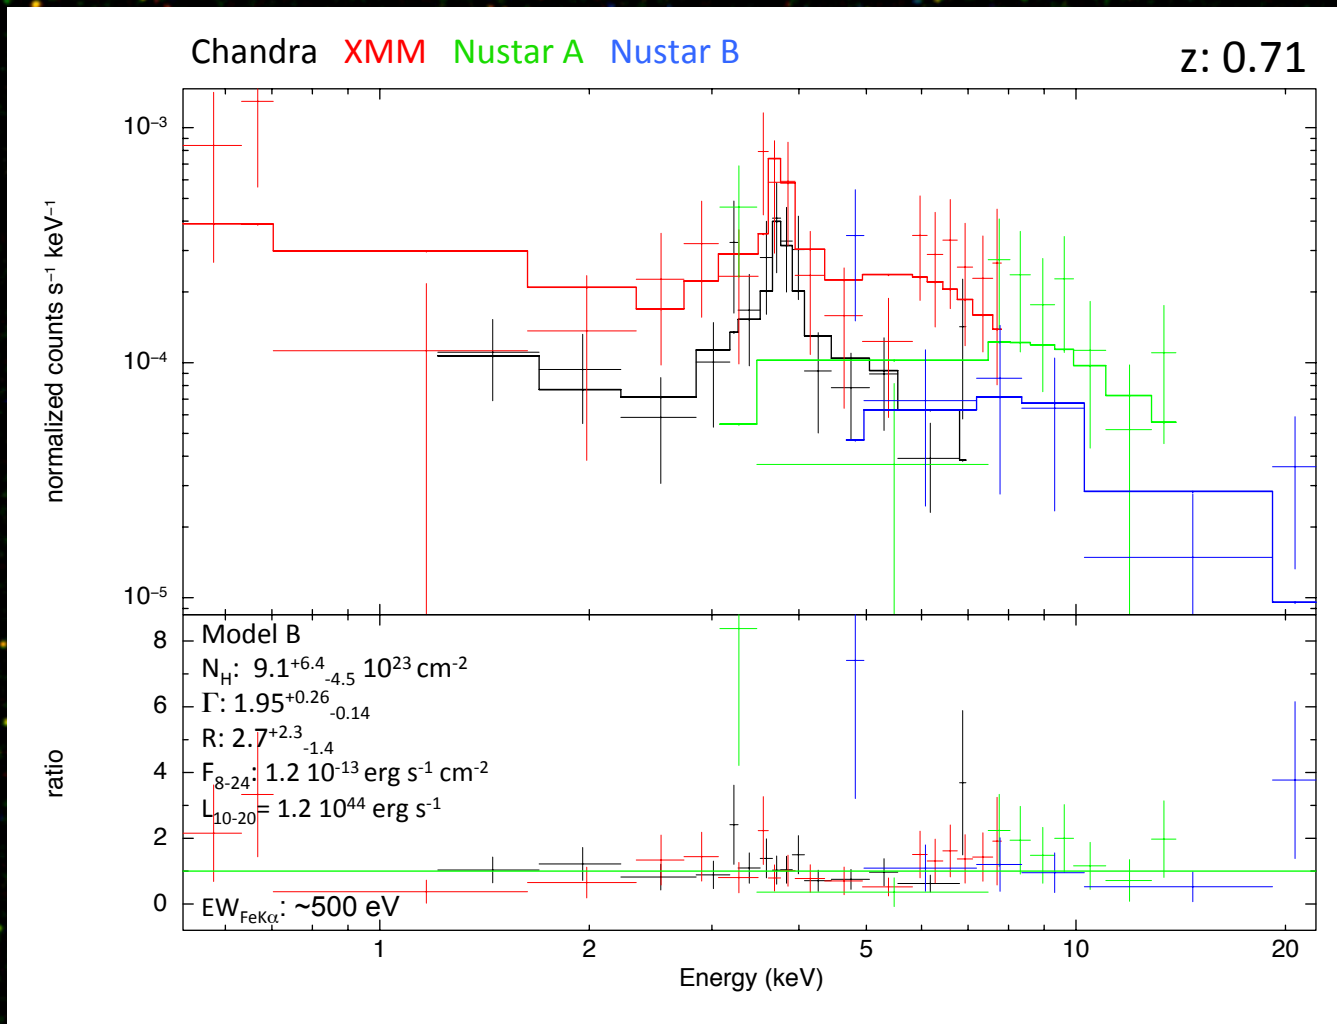

Nustar only

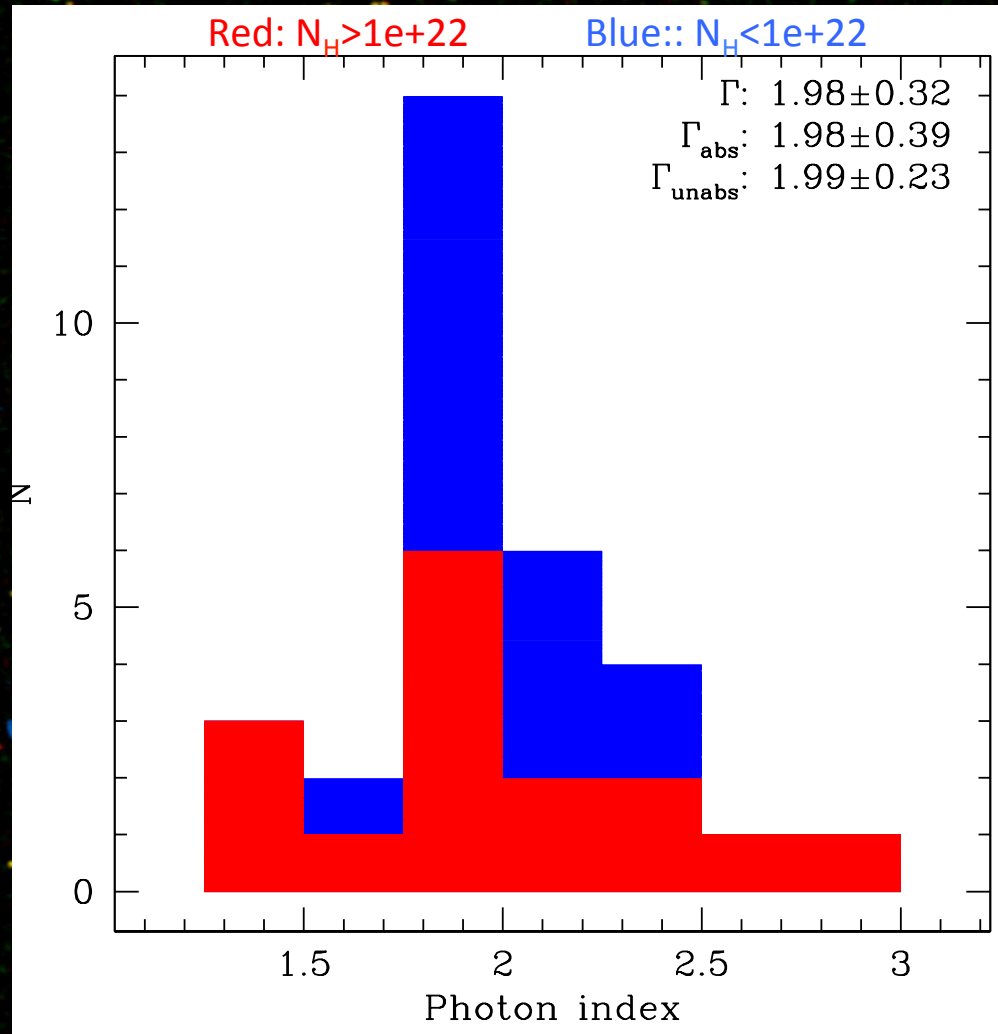

Heavily absorbed sources

Heavily absorbed sources

Photon index distribution

No difference btw
absorbed and
unabsorbed

Photon index vs N_H

Chandra:
 $N_H > 1e+23 \text{ cm}^{-2} \rightarrow 8\%$

Nustar:
 $N_H > 1e+23 \text{ cm}^{-2} \rightarrow 32\%$

Grey objects are Chandra from Lanzuisi et al. 2013

Photon index vs N_H

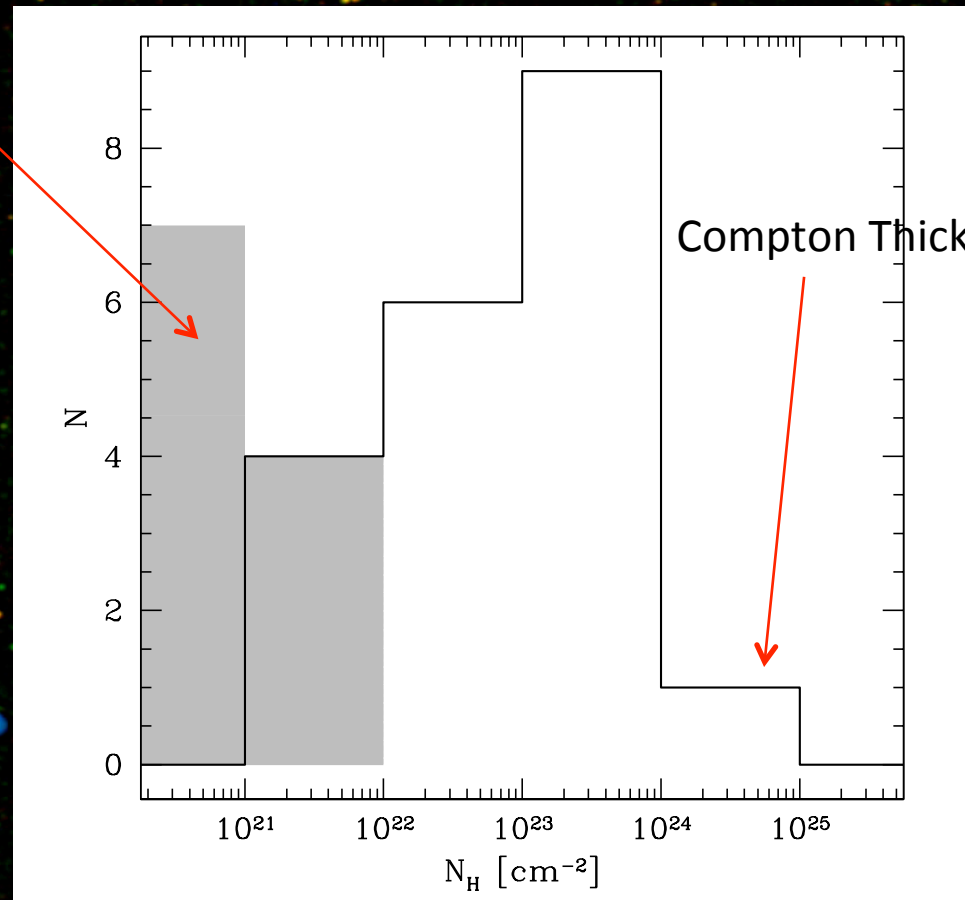

Swift-BAT:
 $N_H > 1e+23 \text{ cm}^{-2} \rightarrow 30\%$

Nustar:
 $N_H > 1e+23 \text{ cm}^{-2} \rightarrow 32\%$

Grey objects are SWIFT-BAT from Burlon et al. 2011

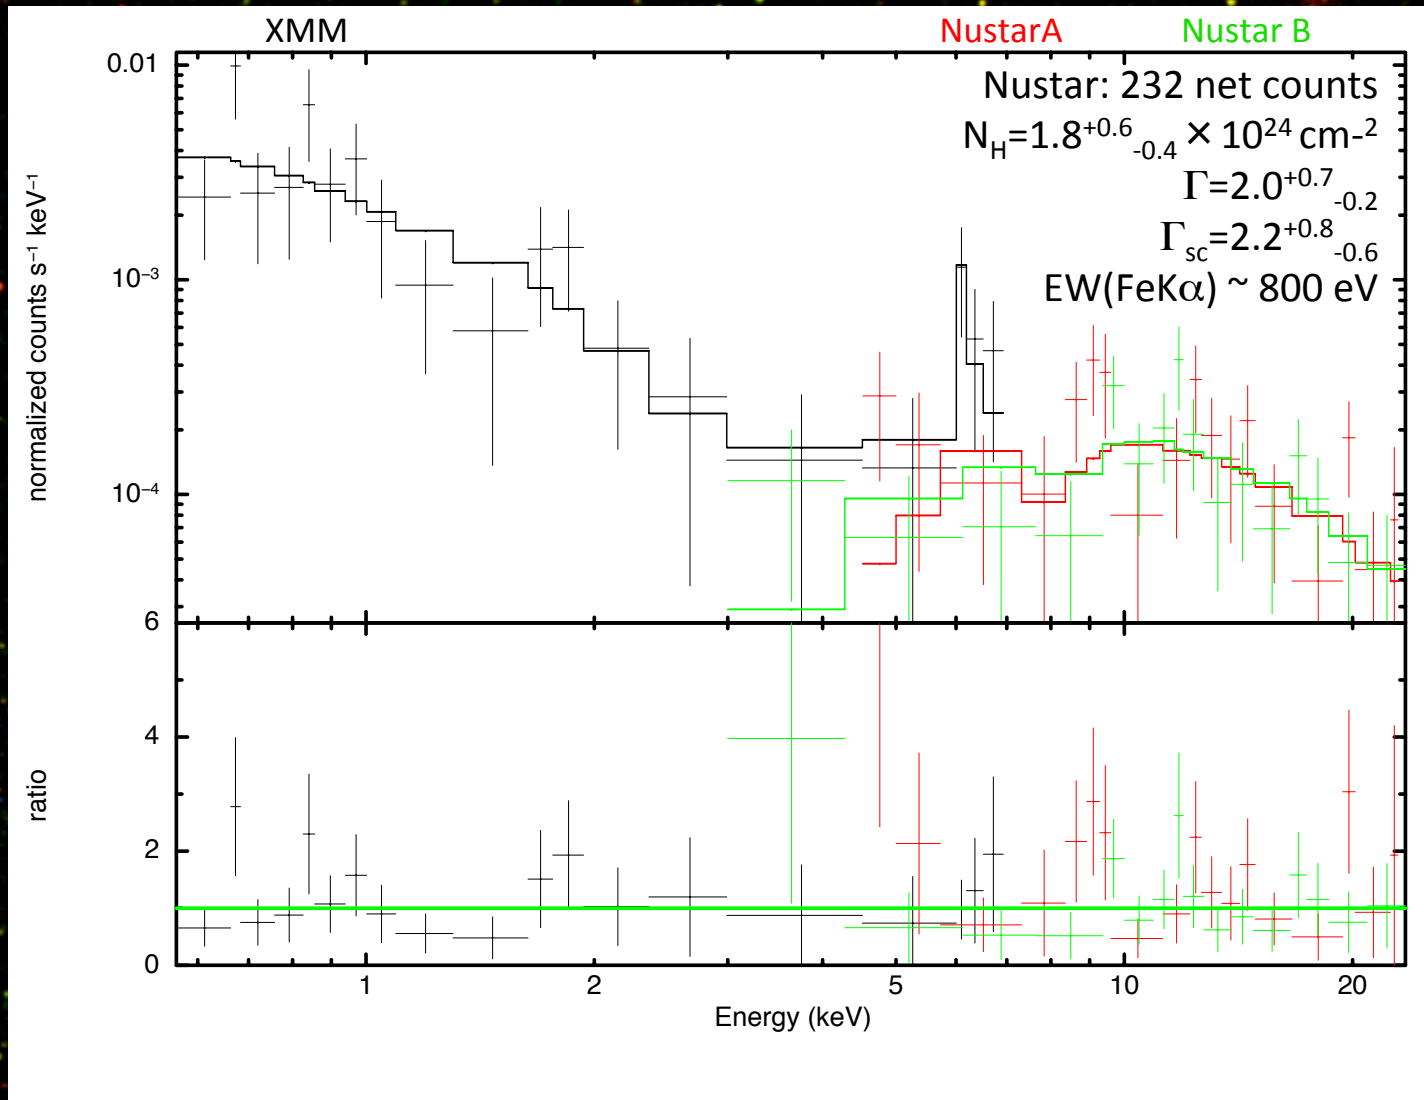

Column density distribution

Upper limits

- $N_H > 1e+23 \text{ cm}^{-2} \rightarrow 10/31 = 32\%$
- $N_H < 1e+23 \text{ cm}^{-2} \rightarrow 21/31 = 68\%$

The Compton thick source ($z=0.044$)

Luminosity vs. absorption

Median luminosity
For absorbed
 $1.4 \times 10^{44} \text{ erg s}^{-1}$

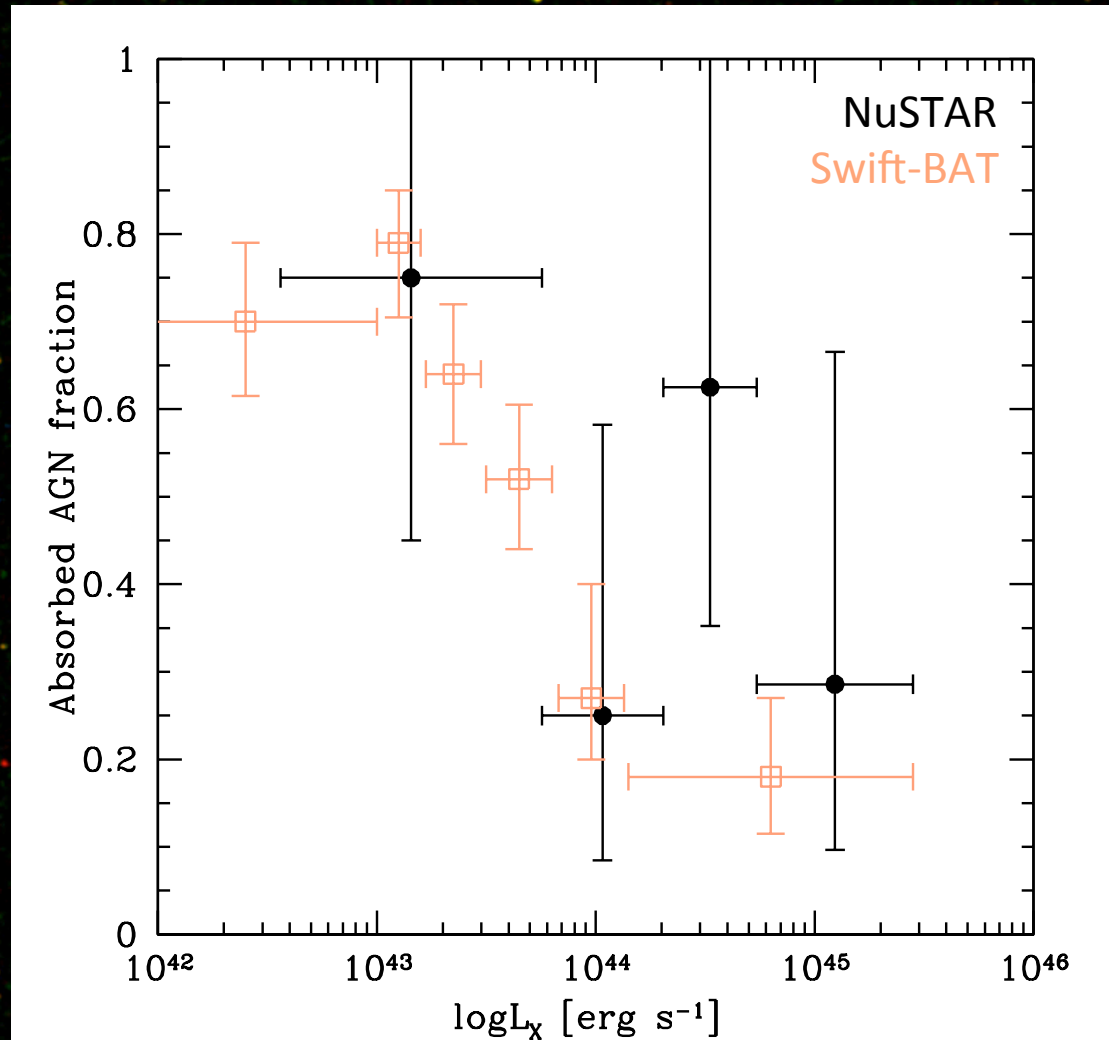

Fraction of obscured
AGNs decreases
with luminosity
(Lawrence & Elvis 1982,
Treister & Urry 2006, Brusa
et al 2010)

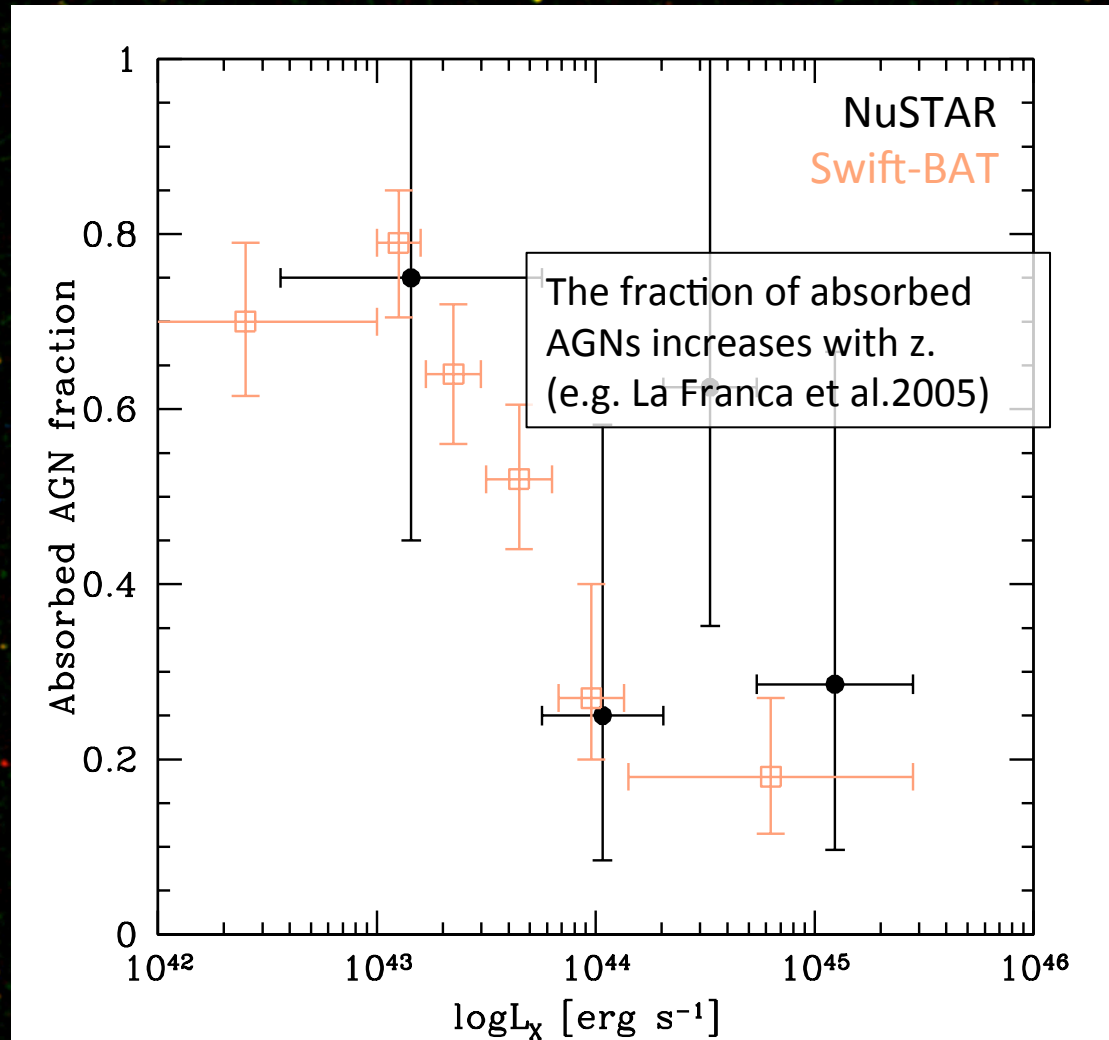

Lack of
objects

Median luminosity
for unabsorbed
 $2.8 \times 10^{44} \text{ erg s}^{-1}$

Fraction of absorbed AGNs

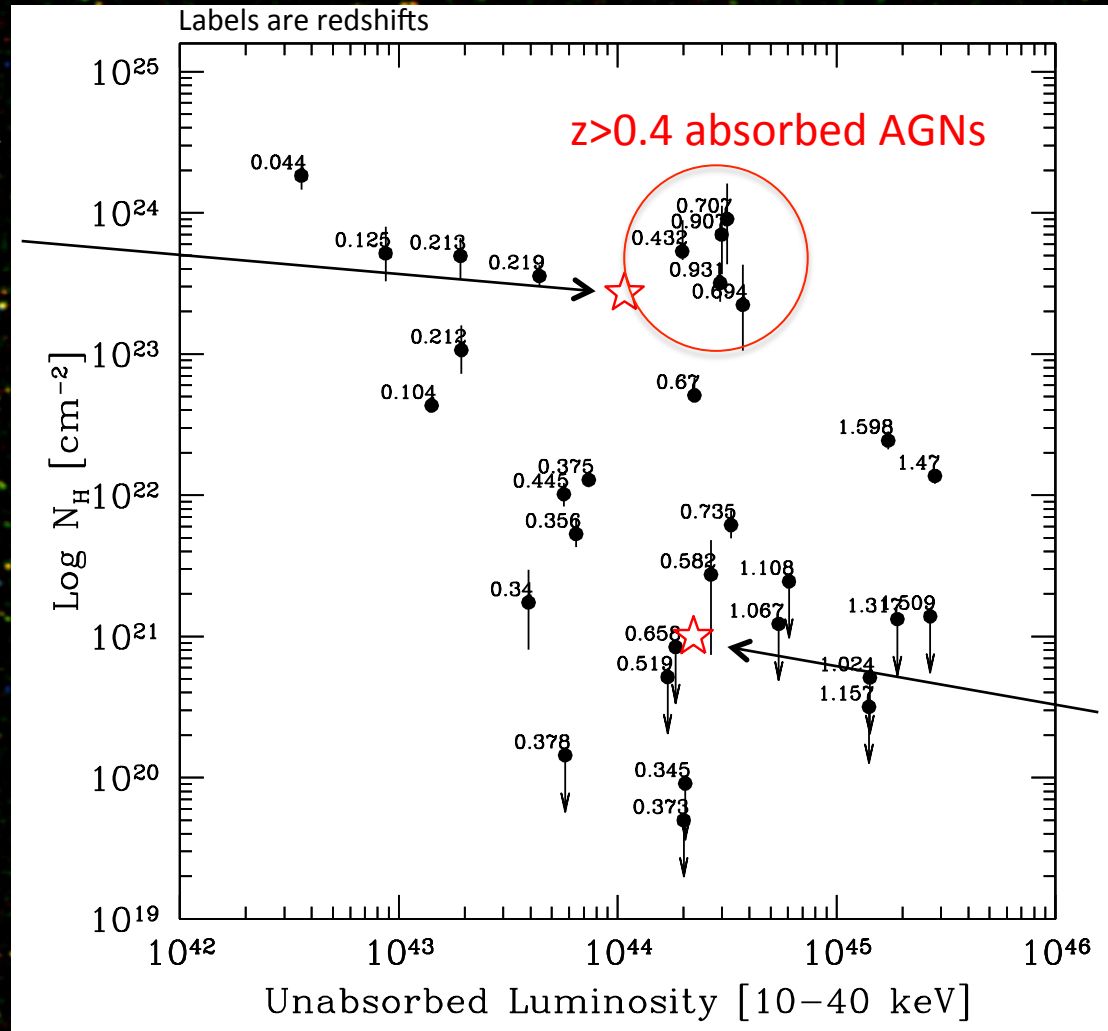

Fraction of absorbed AGNs

Luminosity vs. absorption

Median luminosity
for absorbed
 1.4×10^{44} erg s⁻¹

Median luminosity
for unabsorbed
 2.8×10^{44} erg s⁻¹

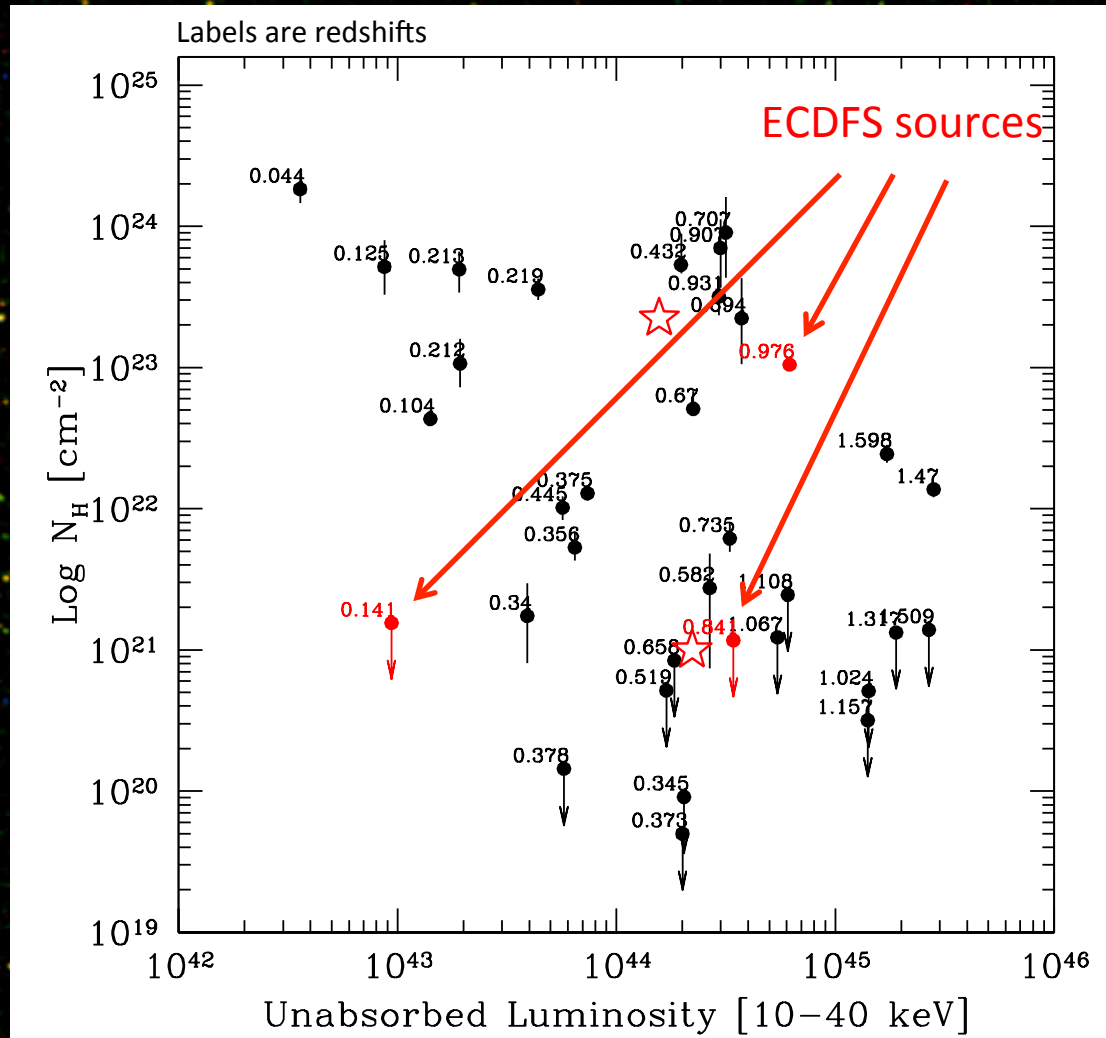

Luminosity vs. absorption

Median luminosity
for absorbed
 $1.9 \times 10^{43} \text{ erg s}^{-1}$

Median luminosity
for unabsorbed
 $6.4 \times 10^{43} \text{ erg s}^{-1}$

Luminosity vs. absorption

Conclusions

- Bright hard (8-24 keV) X-ray selected sample in COSMOS+ECDFS (the most significantly detected sources)
- Sample of 35 non local ($z>0.1$) AGNs
- Ongoing broad band (0.5-24 keV) spectral analysis for the (XMM-Chandra-Nustar)
- Characterization of the spectral properties:
 - Γ : $\sim 2 \pm 0.3$
 - N_{H} : so far $\sim 30\%$ of highly obscured sources (1 of which Compton Thick)
 - R: mean value $\sim 2-3$ with large scatter (consistency with SWIFT-BAT)
 - Slight tendency for AGN absorbed fraction decrease with L_x (probably the redshift dependence is somewhat masking this trend)
